

The flow problem as a LP problem

We let x_e be the flow on edge e . We have the constraints $0 \leq x_e \leq c(e)$ for all e . For each node x except s and t we have

$$\sum_{e \in In(x)} x_e = \sum_{e \in Ut(x)} x_e$$

We set

$$v = \sum_{e \in Ut(s)} x_e$$

The flow problem can be written as

Maximize v

when

$$\begin{cases} v = \sum_{e \in Ut(s)} x_e \\ \sum_{e \in In(x)} x_e = \sum_{e \in Ut(x)} x_e \\ 0 \leq x_e \leq c(e) \end{cases} \quad \begin{array}{l} \text{for all } x \text{ except } s, t \\ \text{for all edges} \end{array}$$

A transport problem

The company Carla produces milk in 4 different plants. The milk is delivered to 5 customers. Carla has to consider three things:

1. The capacities of the plants.
2. The demands of the customers.
3. The costs of the transports between plants and customers.

Let us call the plants F1, F2, F3, F4.

Capacity:

F1	F2	F3	F4
30	40	30	40

(The numbers represent 1000 liters.)

Let us call the customers K1, K2, K3, K4, K5.

Demand:

K1	K2	K3	K4	K5
20	30	15	25	20

(The numbers represent 1000 liters.)

Transport costs:

	K1	K2	K3	K4	K4
F1	2,80	2,55	3,25	4,30	4,35
F2	4,30	3,15	2,55	3,30	3,50
F3	3,00	3,30	2,90	4,30	3,40
F4	5,20	4,45	3,50	3,75	2,45

Goal:

Decide how the "flow" to the customers should be so that

1. The customers are satisfied.
2. The cost are minimal.

Mathematical model:

Use variables x_{ij} for the flow from plant i to customer j .

What demands do we have?

1. Capacities

Ex: For plant 1 we should have

$$x_{11} + x_{12} + x_{13} + x_{14} + x_{15} \leq 30000$$

2. Demand

Ex: For customer 1 we should have

$$x_{11} + x_{21} + x_{31} + x_{41} = 20000$$

Cost:

$$z = 2,80x_{11} + 2,55x_{12} + \dots + 2,45x_{45}$$

We use the following definitions:

Let c_{ij} be the cost for transport from plant i to customer j .

Let s_i be the capacity for plant i .

Let d_j be the demand of customer j .

The problem can now be written as

Minimize $\sum_{i=1}^4 \sum_{j=1}^5 c_{ij} x_{ij}$

when

$$\begin{aligned} \sum_{j=1}^5 x_{ij} &\leq s_i \quad i = 1, 2, 3, 4 \\ \sum_{i=1}^4 x_{ij} &= d_j \quad j = 1, 2, 3, 4, 5 \\ x_{ij} &\geq 0 \end{aligned}$$

Linear Programming

A Linear Programming problem is the following:

Input: We have n variables x_1, x_2, \dots, x_n and m linear equalities and/or inequalities in the variables. We can also have constraints that say that some (all) of the variables should be non-negative. We are given a linear function f in the variables.

Goal: We want to find values for the variables so that the constraints are fulfilled and the function f is optimized (maximized/minimized).

Different forms

We can express an LP-problem on different forms. We have

1. General form: That is the one described above.
2. Canonical form: Essentially a form with just inequalities. This form is suitable for analyzing mathematical properties of solutions.
3. Standard form: Essentially a form with just equalities. This form is used when actually finding solutions.

The general form covers all LP-problems. But all problems can in a certain way be translated to equivalent problems on canonical and standard forms.

Canonical Form

A linear programming problem on canonical form is

$$\text{Minimize } \sum_{j=1}^n c_j x_j$$

when

$$\begin{aligned} \sum_{j=1}^n a_{ij} x_j &\leq b_i \quad i = 1, 2, \dots, m \\ x_j &\geq 0 \end{aligned}$$

In some texts the authors use maximization instead of minimization. This doesn't matter much since we can always translate one form to the other by changing the sign of the c_i :s.

Translations

If we have a problem that is not on canonical form we can rewrite it on canonical form. We show how it can be done by looking at some examples:

Example:

Minimize

$$x_1 + 2x_2 - x_3$$

when

$$\begin{cases} x_1 + x_3 = 1 \\ x_2 - x_3 \geq 3 \end{cases}$$

Inequalities "in the wrong direction" can be turned right by a sign change.

Equalities can be turned into inequalities by using two using two inequalities for each equality.

In our problem we get

Minimize

$$x_1 + 2x_2 - x_3$$

when

$$\begin{cases} x_1 + x_3 \leq 1 \\ -x_1 - x_3 \leq -1 \\ x_3 - x_2 \leq -3 \end{cases}$$

Towards solutions: Standard forms

Preparation: We transform the problem to so called standard form.

Standard form: We have equalities instead of inequalities.

Ex:

Minimize $z = 3x_1 + 5x_2 - x_3$

when

$$x_1 - x_2 + 2x_3 = 5$$

$$x_1 + 2x_2 + 4x_3 = 12$$

$$x_1, x_2, x_3 \geq 0$$

We get equalities by introducing Slack Variables.

Ex:

Let us assume that we have the inequality

$$x_1 + 3x_2 \leq 10$$

We set $x_3 = 10 - (x_1 + 3x_2)$

x_3 is a new slack variable.

We get the equality $x_1 + 3x_2 + x_3 = 10$

The Simplex Method

There is a famous algorithm called the Simplex Algorithm that solves these problems. We will describe this algorithm without going too much into details.

Preparation: We transform the problem to so called standard form

Standard form: We have equalities instead of inequalities.

Let us assume that we have the following problem:

$$\text{Maximize } z = 20x_1 + 18x_2$$

when

$$x_1 + 10x_2 \leq 3600$$

$$16x_1 + 12x_2 \leq 5400$$

$$x_1, x_2 \geq 0$$

$$7x_1 + 10x_2 \leq 3600 \text{ reduces to } 7x_1 + 10x_2 + x_3 = 3600$$

$$16x_1 + 12x_2 \leq 5400 \text{ reduces to } 16x_1 + 12x_2 + x_4 = 5400$$

We get

$$\text{Maximize } z = 20x_1 + 18x_2$$

when

$$7x_1 + 10x_2 + x_3 = 3600$$

$$16x_1 + 12x_2 + x_4 = 5400$$

$$x_1, x_2, x_3, x_4 \geq 0$$

Standard form

Minimize $z = \sum_{j=1}^n c_j x_j$

when

$$\sum_{j=1}^n a_{ij} x_j = b_i \quad i = 1, \dots, m$$

$$x_j \geq 0 \quad j = 1, \dots, n$$

We can use matrix notation

Minimize $\bar{c}^T \bar{x}$

when

$$A\bar{x} = \bar{b}$$

$$\bar{x} \geq \bar{0}$$

Our previous example will look like:

$$A = \begin{pmatrix} 7 & 10 & 1 & 0 \\ 16 & 2 & 0 & 1 \end{pmatrix}$$

$$\bar{x} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \quad \bar{c} = \begin{pmatrix} -20 \\ -18 \\ 0 \\ 0 \end{pmatrix} \quad \bar{b} = \begin{pmatrix} 3600 \\ 5400 \end{pmatrix}$$

$$\text{Minimize} \quad (-20 \quad -18 \quad 0 \quad 0) \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix}$$

when

$$\begin{pmatrix} 7 & 10 & 1 & 0 \\ 16 & 2 & 0 & 0 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} 3600 \\ 5400 \end{pmatrix}$$

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \geq \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

How to find a solution

Maximize $z = 20x_1 + 18x_2$.

When

$$7x_1 + 10x_2 + x_3 = 3600$$

$$16x_1 + 12x_2 + x_4 = 5400$$

How do we find the best solution?

One possibility is $x_3 = x_4 = 0$

$$7x_1 + 10x_2 = 3600$$

$$16x_1 + 12x_2 = 5400$$

If we solve the system we get $x_1 \approx 142$, $x_2 \approx 260$

It gives us $z \approx 7520$

But instead, we can put $x_2 = x_4 = 0$

We get the equations

$$7x_1 + x_3 = 3600$$

$$16x_1 = 5400$$

They give us $x_1 \approx 337$ $x_3 \approx 1237$

Then $z \approx 2362$.

Are there more solutions?

Basic solution:

Let us assume that we have n variables and m equations. We also assume that all equations are linearly independent. We can say that we have set $n - m$ of the variables to 0.

Then the other m variables have unique values. This gives us a basic solution .

Feasible basic solution:

If all variables are ≥ 0 we have a feasible basic solution.

The solution to a LP-problem is always a feasible basic solution (FBS).

But which FBS?

We can write

$$x_3 = 3600 - 7x_1 - 10x_2$$

$$x_4 = 5400 - 16x_1 - 12x_2$$

$$x_1 = 0,158x_3 - 0,132x_4 + 142,1$$

$$x_2 = -0,2x_3 + 0,092x_4 + 260,5$$

$$\begin{aligned} \text{That gives us } z &= 20x_1 + 18x_2 = 20(0,15x_3 \\ &- 0,13x_4 + 142,1) + 18(-0,21x_3 + 0,09x_4 + \\ &260,5) = \\ &7520 - 0,62x_3 - 0,98x_4 \end{aligned}$$

Now we see that we would gain nothing by increasing x_3 or x_4 .

We see that any change from this solution must end in a worse solution.

General description of the Simplex Method

Let's say that we have a maximization problem and a FBS with basic variables y_1, y_2, \dots, y_m and non-basic variables v_1, v_2, \dots, v_{n-m} .

This means that $v_1 = v_2 = \dots = v_{n-m} = 0$

We can then write y_1, y_2, \dots, y_m as functions of v_1, v_2, \dots, v_{n-m}

$$y_1 = f_1(v_1, \dots, v_{n-m})$$

$$y_2 = f_2(v_1, \dots, v_{n-m})$$

...

In the same way we can write z as

$$z = c_1 v_1 + c_2 v_2 + \dots + c_{n-m} v_{n-m} + z_0$$

If all c_i are < 0 we must have an optimal solution.

If any $c_i > 0$, say $c_1 > 0$, we can increase z by increasing v_1 . But then the values of the y :s must change. How much do they change?

We can increase v_1 until $f_k(v_1, v_2, \dots) = 0$ for some k . Then v_1 will be a new basic variable and y_k will be a new non-basic variable.

We go on like this until all $c_i \leq 0$. Then we have found the optimal solution.

If we have a minimization problem we must try to increase variables with $c_i < 0$. When all $c_i \geq 0$ we have a solution.

Ex:

$$\text{Minimize } z = 2x_1 + 2x_2 + x_3$$

when

$$x_1 + x_2 + x_3 = 5$$

$$x_1 - x_2 + 2x_3 = 8$$

$$x_1, x_2, x_3 \geq 0$$

One FBS is $x_2 = 0$ (non-basic variable).

We get

$$x_1 + x_3 = 5 - x_2$$

$$x_1 + 2x_3 = 8 + x_2$$

$$x_1 = 2 - 3x_2$$

$$x_3 = 3 + 2x_2$$

$$z = 2(2 - 3x_2) + 2x_2 + (3 + 2x_2) = 7 - 2x_2$$

We can increase x_2 . But how much?

x_1 and x_3 must be ≥ 0 .

$$x_1 = 2 - 3x_2$$

This means $x_2 \leq \frac{2}{3}$

$$x_3 = 3 + 2x_2$$

This gives us no bound on x_2 .

So $x_2 = \frac{2}{3}$ and $x_1 = 0$.

$$x_3 = \frac{13}{3}$$

We now write x_2 , x_3 as functions of x_1 .

$$x_2 = \frac{2}{3} - \frac{x_1}{3}$$

$$x_3 = 3 + 2x_2 = 3 + 2\left(\frac{2}{3} - \frac{x_1}{3}\right) = \frac{13}{3} - \frac{2x_1}{3}$$

$$z = 7 - 2x_2 = 7 - 2\left(\frac{2}{3} - \frac{x_1}{3}\right) = \frac{17}{3} + \frac{2x_1}{3}$$

Since we gain nothing by increasing x_1 , we are done.

This is however far from the full story. There is a problem called degeneracy that can occur. This happens when when we have no $c_i > 0$ and some $c_i = 0$ (if we assume that we have a minimization problem). In that case we will have to chose some i with $c_i = 0$. Then there is a chance that we could get into an infinite cycle. In practice, there are several ways to avoid this. Another problem is how to find a starting point for the algorithm. It turns out that we can use a modified variant of the simplex algorithm to solve this problem.

Actually, in worst case, the Simplex Algorithm is not a polynomial time algorithm. In practice, however, it is always considered efficient enough to be used.

Dual Problems

For each LP problem we can give a so called dual problem.

Ex: We have the problem

Maximize $5x_1 + 2x_2$

when

$$x_1 + x_2 \leq 10$$

$$2x_1 + 3x_2 \leq 20$$

$$x_1, x_2, x_3 \geq 0$$

The dual problem is

$$\text{Minimize } 10v_1 + 20v_2$$

when

$$v_1 + 2v_2 \geq 5$$

$$v_1 + 3v_2 \geq 2$$

$$v_1, v_2 \geq 0$$

How do we define the dual problem?

Definition of dual problems

We write the problem on the form

$$\text{Maximize } \bar{c}^T \bar{x}$$

when

$$A\bar{x} \leq \bar{b}$$

$$\bar{x} \geq \bar{0}$$

The dual problem is

$$\text{Minimize } \bar{b}^T \bar{v}$$

when

$$A^T \bar{v} \geq \bar{c}$$

$$\bar{v} \geq \bar{0}$$

The Duality Theorem

Let P_1 and P_2 be two dual problems. If one of the problems has a unique solution with value M , then the other problem also has a unique solution with value M . If we solve one of the problems we also get a solution to the other.

Our previous example:

We want to

Maximize $20x_1 + 18x_2$

when

$$7x_1 + 10x_2 \leq 3600$$

$$16x_1 + 12x_2 \leq 5400$$

$$x_1, x_2 \geq 0$$

The corresponding dual problem is

$$\text{Minimize } 3600v_1 + 5400v_2$$

when

$$7v_1 + 16v_2 \geq 20$$

$$10v_1 + 12v_2 \geq 18$$

$$v_1, v_2 \geq 0$$

Both problems have the same value as solution.

Classical example: The diet problem

Suppose that you want to buy food. You have the choice of n types of food which can have some of m different nutrients.

Let

a_{ij} be the amount of i th nutrient in a unit of the j th food.

r_i be the yearly requirement of i th nutrient.

x_j be the yearly consumption of the j th food.

c_j be the cost per unit of the j th food.

Then you (probably) face the problem:

Minimize $\bar{c}\bar{x}$

when

$$A\bar{x} \geq \bar{r}$$

$$\bar{x} \geq 0$$

The dual problem

The dual problem is then

Maximize $\bar{r}\bar{w}$

when $A^T\bar{w} \leq \bar{c}$

$\bar{w} \geq 0$

What does this mean? A possible application is that we have a store who wants to sell m pills containing all the nutrients. Let w_i be the price he sets for pill i (containing nutrient i). In order for the pills to be competitive with real food he must make sure that $A^T\bar{w} \leq \bar{c}$. He also wants to maximize his profit, i.e. $\bar{r}\bar{w}$.

About solutions to LP problems

If we try to solve a LP problem three cases can occur.

1. The problem has a unique solution.
2. The inequalities defining the problem cannot be satisfied.

Ex: Minimize $x_1 + x_2$

when

$$x_1 - 2x_2 \leq -2$$

$$x_1 + 3x_2 \leq 1$$

$$x_1, x_2 \geq 0$$

Then, of course, there is no solution to the problem.

3. The value can be arbitrarily large/small.

Ex: Maximize $x_1 - x_2$

when

$$x_1 + x_2 \geq 10$$

$$x_1, x_2 \geq 0$$

The problem is that $x_1 - x_2$ can be arbitrarily large. There is no solution.

Part of what the Duality Theorem tells us is that if one of two dual problems is of type 1, the other one must be of type 1 as well.

Reduction of Shortest Path to Linear Programming

Find the shortest path $s \rightarrow t$ in a weighted (undirected) graph G .

We can define variables x_e (one for each edge). We can see that this LP-problem solves the Shortest Path-problem:

Minimize

$$\sum_e x_e w(e)$$

when

$$\begin{cases} 1 = \sum_{e \in U_t(s)} x_e \\ 1 = \sum_{e \in I_n(t)} x_e \\ \sum_{e \in I_n(x)} x_e = \sum_{e \in U_t(x)} x_e & \text{for all } x \text{ except } s, t \\ 0 \leq x_e \text{ for all edges} \end{cases}$$

The dual form

Dualization will give us variables d_v (one for each node). Without going into details we state the dual form:

Maximize d_t

when

$$\begin{cases} d_u \leq d_v + w(u, v) & \text{for all edges } (u, v) \\ d_s = 0 \end{cases}$$

Another dual problem

The flow problem can be put on dual form:

The vector \bar{y} contains $|V| + |E|$ numbers. They are g_i for each node v_i and γ_j for each edge e_j .

Minimize

$$\sum_j \gamma_j c_j$$

when

$$\begin{cases} g_i - g_j + \gamma_k \geq 0 & \text{om } e_k = (v_i, v_j) \\ g_n - g_1 \geq 1, \quad \gamma_j \geq 0 & \text{for all } j \end{cases}$$

The solution to this problem generates a minimal cut $(S, V - S)$ and an assignment of values $g_i = 0$ if $v_i \in S$, $g_i = 0$ otherwise. $\gamma_j = 1$ if e_j goes from S to $V - S$, $\gamma_j = 0$ otherwise.

Other types of problems

Several of the problems we have seen are of integer character in the sense that the solutions have the form: Choose this object (1) and do not choose that object (0). But LP mostly gives solutions that are real numbers. We can define a new set of LP-problems called Integer Programming Problems by demanding that the solutions should have integer values.

Ex: Minimal spanning trees.

We can start with the LP-problem

Minimize

$$\sum_e x_e w(e)$$

when

$$\begin{cases} \sum_{e \in In(v)} x_e \geq 1 & \text{for all nodes } v \\ \sum_e x_e = |V| - 1 \end{cases}$$

This will almost give us a MST. But we must add the requirement that all x_e should be 0 or 1. We can write this as

$$x_e \in \{0, 1\} \text{ for all edges}$$

This gives us an Integer Programming Problem.

Subset Sum

We can look at the special problem

$A = \{2, 7, 9, 12, 16\}$ and $M = 23$ and ask M can be written as a sum of elements from A .

We can then state the following IP-problem:

Maximize 1

when

$$\begin{cases} 2x_1 + 7x_2 + \dots + 16x_5 = 23 \\ x_i \in \{0, 1\} \end{cases}$$

Even if it is nice to be able to state the problem as an IP-problem there is a catch: There is no known efficient algorithm for solving IP-problems!
